Field evaluation of fungicides for management of Mycosphaerella (Ascochyta) blight on field peas
Carrington, ND (2013)

Michael Wunsch, plant pathologist
Michael Schaefer, research specialist
Billy Kraft, research technician
North Dakota State University Carrington Research Extension Center

SUMMARY OF KEY RESULTS:

Michael Wunsch, plant pathologist
Michael Schaefer, research specialist
Billy Kraft, research technician
North Dakota State University Carrington Research Extension Center

KEY FINDINGS:
- The registered fungicides Headline (6 fl oz/ac), Proline (5.7 fl oz/ac), and ProPulse (8 fl oz/ac) provided excellent control of Mycosphaerella blight.
- The fungicide Omega (anticipated registration on peas in 2017) performed similarly when applied at 0.5, 0.675, and 0.85 pt/ac, suggesting that the low application rate of 0.5 pt/ac may be sufficient.
- Due to late disease onset (Mycosphaerella blight did not reach high levels until late pod-fill), disease control did not result in increased seed yield.

Active ingredients of products tested in this trial:
- Omega: 500 grams fluzinam per liter
- Headline: 250 grams pyraclostrobin per liter
- Proline: 480 grams prothioconazole per liter
- ProPulse: 200 grams prothioconazole + 200 grams fluopyram per liter

</table>

Canopy necrosis: Percent of the canopy exhibiting necrosis caused by foliar disease. Mycosphaerella/Ascochyta blight was the only foliar disease present above trace levels.

Diseased pods: Percent of the pods with disease lesions exceeding approx. 1 mm diameter. Mycosphaerella/Ascochyta blight was the only pod disease present above trace levels.

Harvest ease: A measure of lodging. At harvest, the peas were evaluated for ease of harvest; a 1 to 9 scale was used, where 1 = perfectly erect and 9 = completely flat.

Fungicide application timing:
- Application A: July 1 at 4:45 to 5:30 pm at early bloom (100% of plants with at least one open blossom), no Mycosphaerella blight present, air temperature = 82°F, relative humidity = 30%, wind speed = 3 to 5 mph.
- Application B: July 14 at 6:45 to 7:45 pm; field peas at end of bloom, Mycosphaerella blight present at low levels (scattered lesions on the bottom 20% of canopy in non-treated control); wind = 3 to 4 mph out of the northeast, 72 to 74°F, 72% relative humidity.

On July 25, the peas were at the late R4 growth stage (green seeds filled the pods at most nodes); on July 31, the peas were at the R5 growth stage (leaves started to turn yellow and lower pods yellow-brown); on Aug. 9, the peas were at the R7 growth stage (physiological maturity - pods yellow to brown).

Within-column means followed by different letters are significantly different (P < 0.05; Tukey multiple comparison procedure).

The fungicides INSPIRE and OMEGA are currently not registered for use on field peas and should not be used.

Future registration of Omega is anticipated, and results are provided for reference only.
Field evaluation of fungicides for management of Mycosphaerella (Ascochyta) blight on field peas

Carrington, ND (2013)

Methods:

- Location of trial: North Dakota State University Carrington Research Extension Center
- GPS coordinates of research location: 47.512, -99.129
- Soil type: Heimdal-Emrick loam
- Rhizobium inoculant: Cell-Tech granular nitrogen fixing inoculant for pea and lentil (Rhizobium leguminosarum biovar viciae, 100 million viable cells per gram; Novozymes BioAg, Saskatoon, SK Canada) was mixed with the seed and applied at a rate of 2 dry ounces per 1000 feet of row (56 grams per 300 meters of row).
- Maintenance herbicide applications: Sonalan HFP (ethalfluralin; Dow AgroSciences) was applied at 2 pts/ac in 11 gallons of water/ac at 8:45 am on May 10. It was manually incorporated twice on May 10, once with a deep cultivation and once with a shallow cultivation.
- Variety: Bridger
- Seed treatment: Stamina (0.4 fl oz/cwt; pyraclostrobin 1.67 lbs ai/gal) + Axcess (1.6 fl oz/cwt; imidacloprid 5 lbs ai/gal)
- Experimental design: randomized complete block
- Replicates: 4
- Seeded plot size: 5 ft (center-to-center) x 25 ft long
- Harvested plot size: 5 ft (center-to-center) x approx. 19 ft long
- Untreated buffer plots were established between treatment plots.
- Row spacing: 7 inches
- Plants per plot: 7
- Planting date: May 12, 2013
- Previous crop: Spring wheat
- Seeding rate: 330,000 pure live seeds/ac. Seeds were planted 1.75 to 2.25 inches deep into moist soil.
- Fungicide application A: July 1 at 4:45 to 5:30 pm at early bloom (100% of plants with at least one open blossom), no Mycosphaerella blight present, air temperature = 82˚F, relative humidity = 30%, wind speed = 3 to 5 mph.
- Fungicide application B: July 14 at 6:45 to 7:45 pm; field peas at end of bloom, Mycosphaerella blight present at low levels (scattered lesions on the bottom 20% of canopy in non-treated control); wind = 3 to 4 mph out of the northeast, 72 to 74˚F, 72% relative humidity.
- Fungicide application details: Fungicides were applied with a 56-inch hand boom equipped with four equally spaced Spraying Systems TeeJet XR 8001VS flat-fan nozzles at a spray volume of 15 gal water/A operated at 35 psi.
- Disease establishment: Grain-based Ascochyta inoculum was generated by soaking wheat, autoclaving the soaked wheat, and inoculating the autoclaved wheat with a spore solution harvested from 4-week-old cultures of Ascochyta pisi and A. pinodes (Mycosphaerella pinodes) isolated from diseased field peas. The autoclaved grain was inoculated on June 4. Grain-based Ascochyta inoculum was applied to the buffer and guard plots at an application rate of 2.65 ml per square foot at 9:00 to 9:30 am on July 2, 2013 and at an application rate of 5 ml per square foot at 9:00 to 9:45 pm on July 13, 2013. On July 2, overhead irrigation commenced 30 minutes later; 1 inch of water was applied. On July 13, overhead irrigation commenced approximately 6 hours later; 0.5 inch of water was applied.
- Disease assessment: Disease severity was evaluated as the percent of the canopy exhibiting necrosis caused by foliar disease and the percent of the pods with disease lesions exceeding approx. 1 mm diameter. Mycosphaerella/Ascochyta blight was the only disease present above trace levels.
- Harvest ease: A measure of lodging. At harvest, the peas were evaluated immediately before harvest on August 9 for lodging; a 1 to 9 scale was used, where 1 = perfectly erect and 9 = completely flat.
- Harvest date: August 9, 2013
- Statistical analysis: Data were evaluated with analysis of variance. The assumption of constant variance was assessed by plotting residuals against predicted values, and the assumption of normality was assessed with a normal probability plot. All data met model assumptions. Single-degree-of-freedom contrasts were performed for all pairwise comparisons of isolates; to control the Type I error rate at the level of the experiment, the Tukey multiple comparison procedure was employed. Analyses were conducted with replicate and treatment as main factor effects, and they were implemented in PROC GLM of SAS (version 9.2; SAS Institute, Cary, NC).

Funding:

This project was funded by ISK BioSciences and Bayer Crop Science. BASF donated the seed treatment products used in this trial.

Important notice:

- Fungicide performance can differ in response to which diseases are present, levels of disease when products are applied, environmental conditions, plant architecture and the susceptibility to disease of the variety planted, crop growth stage at the time of fungicide application, and other factors.
- This report summarizes fungicide performance as tested at the NDSU Carrington Research Extension Center under the conditions partially summarized in the methods section (above).
- Fungicide efficacy may differ under other conditions; when choosing fungicides, always evaluate results from multiple trials.
- This report is shared for educational purposes and is not an endorsement of any specific products.
